## Job Market Paper

### The Impact of Batching Advanced Imaging Tests in Emergency Departments

**PREPRINT**

**Jameson, J. C.**, Saghaian, S., Huckman, R. S., Hodgson, N., & Baugh, J.

*Invited for 2nd round revise-and-resubmit at Management Science*

Using detailed electronic health record data of over 150,000 patient encounters from two major U.S. emergency departments (EDs), we examine practice variation across physicians to uncover the operational impact of discretionary batch ordering of imaging tests. We find that quasi-random assignment of a patient to an ED physician with a higher tendency to batch causally increases the patient's length of stay, time to disposition, and the number of imaging tests performed. Discretionary batching increases length of stay by approximately 76%, increases time to disposition by approximately 88%, increases imaging by 0.91 tests per encounter, and has no detectable effect on 72-hour returns requiring admission. Results suggest that discretionary batching may lead to clinical decision-making that introduces bottlenecks in patient flow. Put together, our findings indicate that discretionary batch ordering is not an efficient strategy for managing diagnostic imaging in emergency care, and interventions to reduce unnecessary batching may improve both operational performance and resource utilization.
